HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

FIBRATIONS STRUCTURE AND DEGREE FORMULAE FOR MILNOR FIBERS

N. DUTERTRE, R. ARAÚJO DOS SANTOS, Y. CHEN AND A. ANDRADE

ABSTRACT. In this survey, we remind some fibrations structure theorems (also called Milnor's fibrations) recently proved in the real and complex case, in the local and global settings. We give several Poincaré-Hopf type formulae which relates the Euler-Poincaré characteristic of these fibers (also called Milnor's fibers) and indices (topological degree) of appropriated vector fields defined on spheres of radii small or big enough.

1. INTRODUCTION

In this survey, we provide a brief review of some extensions of the real and complex Milnor fibration's theorems for isolated and non-isolated singularities and we give some Poincaré-Hopf type formulae which gives a connection between the Euler-Poincaré characteristic of the (regular) Milnor's fibers and the index of a gradient vector field. The paper is organized as follows. In Section 2, we first remind some fibration structure theorems which extend the very well known complex and real local Milnor's fibrations stated in [Mi]. In the sequel, we remind Milnor's formula for complex isolated singularity (Poincaré-Hopf type formula) and we state several extensions of such formula which has been developed recently for functions and mappings with non-isolated singularities, in the complex and real case.

In Section 3, we try to follow the line of development of Section 1, i.e., we also start introducing and showing some fibrations's Theorems, but now in the global case (at infinity), and in the sequel we show several Poincaré-Hopf type formulae in this setting.

2. FIBRATION STRUCTURE AND DEGREE FORMULAE - LOCAL SETTING

2.1. Milnor's fibrations structure. For a germ of complex holomorphic function $f : (\mathbb{C}^{n+1}, 0) \rightarrow (\mathbb{C}, 0)$, in [Mi, Theorem 4.8, page. 43] Milnor proved that there exists a small enough $\epsilon_0 > 0$ such that for all $0 < \epsilon \leq \epsilon_0$ the projection

$$(1) \quad \frac{f}{\|f\|} : S_\epsilon^{2n+1} \setminus \{f = 0\} \rightarrow S^1$$

is a smooth locally trivial fibration.

Later, it was proved by Lê D. Tráng that the restriction map

$$f| : \mathring{B}_\epsilon^{2n+2} \cap f^{-1}(S_\delta^1) \rightarrow S_\delta^1$$

is also the projection of a locally trivial smooth fibration and that such a fibration is fiber-equivalent to the fibration (1), where $\mathring{B}_\epsilon^{2n+2}$ denotes the interior of the closed ball B_ϵ^{2n+2} .

For a real analytic map germ $F : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$, $n > p \geq 2$ with isolated singularity at origin, Milnor also proved in [Mi, Theorem 11.2, page. 97] that, for all $\epsilon > 0$ small enough, there exists $0 < \eta \ll \epsilon$ such that the restriction map

$$F| : B_\epsilon^n \cap F^{-1}(S_\eta^{p-1}) \rightarrow S_\eta^{p-1}$$

is the projection of a locally trivial smooth fibration (called fibration in the “Milnor tube”), with fiber $\mathcal{M}_F^T := (F|)^{-1}(y)$. He also constructed a convenient vector field in $B_\epsilon^n \setminus V$, where $V = F^{-1}(0)$, and used its flow to push the Milnor tube $B_\epsilon^n \cap F^{-1}(S_\eta^{p-1})$ to the sphere S_ϵ^{n-1} , but keeping the boundary $S_\epsilon^{n-1} \cap F^{-1}(S_\eta^{p-1})$ fixed. Now, since 0 is an isolated critical point of F , it is not hard to see that is possible to extend this fibration to get a smooth locally trivial fibration

$$S_\epsilon^{n-1} \setminus \text{Lk}^0(V) \rightarrow S^{p-1},$$

where $\text{Lk}^0(V) := V \cap S_\epsilon^{n-1}$ is called the link of the zero set V at origin.

As Milnor pointed out, in general we can not expect that the projection of this last fibration will be given by the canonical one $\frac{F}{\|F\|}$. In [AT] the authors provide a characterization of such a fibration in the more general case of non-isolated singularity (see also [RA, Ar, CSS]) as follows.

Theorem 2.1. *Let $F : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$, $n > p \geq 2$ be an analytic mapping and Σ_F its singular locus i.e., the set of points where the gradients $\nabla f_1, \dots, \nabla f_p$ are linearly dependent. Assume that $\Sigma_F \cap V \subseteq \{0\}$. The following two statements are equivalent:*

- (a) *for all $\epsilon > 0$ small enough the projection $\frac{F}{\|F\|} : S_\epsilon^{n-1} \setminus \text{Lk}^0(V) \rightarrow S^{p-1}$ is a smooth locally trivial fibration.*
- (b) *for all $\epsilon > 0$ small enough the projection $\frac{F}{\|F\|} : S_\epsilon^{n-1} \setminus \text{Lk}^0(V) \rightarrow S^{p-1}$ is a smooth submersion.*

We remark that, this equivalence is not so trivial because if the link is not empty such a projection mapping is never proper.

The Milnor tube fibration for non-isolated singularity was established by D. Massey in [Ma] as follows.

Let $F = (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$ be an analytic map, $2 \leq p \leq n-1$, and ρ be the square of the distance function to the origin and denote by $M(F)$ the set of critical points of the pair (F, ρ) , i.e., the set of points where the gradients $\nabla \rho, \nabla f_1, \dots, \nabla f_p$ are linearly dependent. This set is called the *Milnor set* and it also plays an important role in the study of asymptotical behavior of polynomial mappings at infinity, as the reader will see in the next section.

It follows by definition that $\Sigma_F \subseteq M(F)$.

Definition 2.2. [Ma] *Given F and ρ as above.*

- (a) *We say that F satisfies Milnor's condition (a) at the origin, if $\Sigma_F \subset V$ in a neighborhood of the origin.*
- (b) *We say that F satisfies Milnor's condition (b) at the origin, if 0 is isolated in $V \cap \overline{M(F) \setminus V}$ in a neighborhood of the origin, where the notation \overline{X} means the topological closure of the space X .*

Remark 2.3. *It follows from Definition 2.2 the equivalence:*

The mapping F satisfies Milnor's condition (b) at the origin if and only if for each $\epsilon > 0$ small enough, there exist $\delta > 0$, $0 < \delta \ll \epsilon$ such that the restriction map $F| : S_\epsilon^{n-1} \cap F^{-1}(B_\delta^p \setminus \{0\}) \rightarrow B_\delta^p \setminus \{0\}$ is a smooth submersion (and onto, if the link of $F^{-1}(0)$ is not empty).

We say that $\epsilon > 0$ is a *Milnor radius for F at origin*, provided that $B_\epsilon^n \cap (\overline{\Sigma_F} - V) = \emptyset$, and $B_\epsilon^n \cap V \cap (\overline{M(F)} \setminus V) \subseteq \{0\}$, where B_ϵ^n denotes the closed ball in \mathbb{R}^n with radius ϵ .

Consequently, under Milnor's conditions (a) and (b), we can conclude that for all regular values close to the origin the respective fibers into the closed ϵ -ball are smooth and transverse to the sphere S_ϵ^{n-1} .

Theorem 2.4 ([Ma], Theorem 4.3, page 284). *Let $F : (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$ satisfying Milnor's conditions (a) and (b) and $\epsilon_0 > 0$ be a Milnor's radius for F at origin. Then, for each $0 < \epsilon \leq \epsilon_0$, there exist δ , $0 < \delta \ll \epsilon$, such that*

$$(2) \quad F| : B_\epsilon^n \cap F^{-1}(B_\delta^p \setminus \{0\}) \rightarrow B_\delta^p \setminus \{0\}$$

is the projection of a smooth locally trivial fiber bundle.

Proof. (Idea) Since $\epsilon_0 > 0$ is a Milnor's radius for F at origin, we have that $\Sigma_F \cap B_{\epsilon_0}^n \subset V \cap B_{\epsilon_0}^n$. It means that, for all $0 < \epsilon \leq \epsilon_0$ the map $F| : \dot{B}_\epsilon^n \setminus V \rightarrow \mathbb{R}^p$ is a smooth submersion in the open ball \dot{B}_ϵ^n .

From the Milnor condition (b), and the remark above, it follows that: for each ϵ there exists δ , $0 < \delta \ll \epsilon$, such that

$$F| : S_\epsilon^{n-1} \cap F^{-1}(B_\delta^p - \{0\}) \rightarrow B_\delta^p - \{0\}$$

is a submersion on the boundary S_ϵ^{n-1} of the closed ball B_ϵ^n .

Now, combining these two conditions we have that, for each ϵ , we can choose δ such that

$$F| : B_\epsilon^n \cap F^{-1}(B_\delta^p - \{0\}) \rightarrow B_\delta^p - \{0\}$$

is a proper smooth submersion. Applying the Ehresmann Fibration Theorem for the manifold with boundary B_ϵ^n , we get that it is a smooth locally trivial fibration. \square

Corollary 2.5. *(Milnor's fibration in the tube) Let $F : (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$ satisfying Milnor's conditions (a) and (b) and $\epsilon_0 > 0$ be a Milnor's radius for F at origin. Then, for each $0 < \epsilon \leq \epsilon_0$, there exists δ , $0 < \delta \ll \epsilon$, such that*

$$(3) \quad F| : B_\epsilon^n \cap F^{-1}(S_\delta^{p-1}) \rightarrow S_\delta^{p-1}$$

is the projection of a smooth locally trivial fiber bundle.

Example 2.6. *Let $f : (\mathbb{C}^n, 0) \rightarrow (\mathbb{C}, 0)$ be a holomorphic function germ, then it satisfies the Milnor conditions (a) and (b).*

In fact, Milnor's condition (a) and (b) can be seen as an application of Lojasiewicz's inequality which states that, in a small neighborhood of the origin, there are constants $C > 0$ and $0 < \theta < 1$ such that

$$|f(x)|^\theta \leq C \|\nabla f(x)\|.$$

So, Milnor's condition (a) follows. In [HL], page 323, Hamm and Lê proved that the Lojasiewicz inequality implies Thom a_f -condition for a Whitney (a) stratification of V . Therefore, Milnor's condition (b) follows.

Example 2.7. *Let $F : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$ be an analytic map-germ with an isolated singular point at origin. Then, Milnor's conditions (a) and (b) above hold. In fact, Milnor's condition (b) follows since the zero locus is transversal to all small spheres.*

In [AT, ACT1] the authors considered the following definition.

Definition 2.8. [ACT1]. *We say that the pair (K, θ) is a higher open book structure with singular binding on an analytic manifold M of dimension $m - 1 \geq p \geq 2$ if $K \subset M$ is a singular real subvariety of codimension p and $\theta : M \setminus K \rightarrow S_1^{p-1}$ is a locally trivial smooth fibration such that K admits a*

neighbourhood N for which the restriction $\theta|_{N \setminus K}$ is the composition $N \setminus K \xrightarrow{h} B^p \setminus \{0\} \xrightarrow{\pi} S_1^{p-1}$ where h is a locally trivial fibration and $\pi(s, y) = s/\|s\|$.

In such a case, one says that the singular fibered subvariety K is the binding and that the (closures of) the fibers of θ are the pages of the open book.

Let us denote by $M(\frac{F}{\|F\|})$ the singular locus of the pair $(\frac{F}{\|F\|}, \rho)$, where $\rho(x) = x_1^2 + \dots + x_n^2$ is the square of distance function to the origin. Inspired by Milnor's conditions in [Ma], in the paper [ACT1] the authors proved some theorems about fibration structures on spheres of radii small enough for non-isolated singularity, as follows.

Theorem 2.9 ([ACT1], Theorem 1.3, page 819). *Let $F : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$ be a real analytic mapping germ. Assume that Milnor's condition (b) holds and $\text{codim}_{\mathbb{R}} V = p$. If for all $\epsilon > 0$ small enough the set $M(\frac{F}{\|F\|})$ is empty, then the pair $(\text{Lk}^0(V), \frac{F}{\|F\|})$ is a higher open book structure on the spheres S_ϵ^{n-1} , with singular binding. In particular, the projection*

$$(4) \quad \frac{F}{\|F\|} : S_\epsilon^{n-1} \setminus \text{Lk}^0(V) \rightarrow S^{p-1}$$

is a smooth locally trivial fibration.

It seems natural to ask the following question: how does the fibers of fibrations (3) and (4) relates with each other, once both fibrations exist ?

Denote by \mathcal{M}_F^T and $\mathcal{M}_{\frac{F}{\|F\|}}^S$ the fibers of fibrations (3) and (4), respectively. In [CSS] the authors considered a condition called d -regularity and assuming also that F satisfies a Thom a_F -condition, they showed that both fibrations are fiber-equivalent. We should point out that, it is pretty clear that Thom a_F -condition along V imply Milnor's condition (b). But, the converse is not true as the reader can check in [ACT1], section 5.3, page 827, in an example provided by A. Parusinsky.

More recently, just assuming Milnor's condition (b) and using a quite different machinery, the authors in [DACA] proved a similar result to the one stated in [CSS]. This result was proved first by M. Oka in [Ok] for non-degenerate and convenient mixed polynomial germs.

Proposition 2.10 ([DACA], section 5.0.1, Proposition 5.2). *Let $F = (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$ be a real analytic map germ satisfying Milnor's conditions (a) and (b). If $M(\frac{F}{\|F\|})$ is empty (as a germ of set), then the two fibers \mathcal{M}_F^T and $\mathcal{M}_{\frac{F}{\|F\|}}^S$ are homotopy equivalent.*

At this point, we would like to invite the interested reader to look at section 5.0.1 of [DACA] for further details.

2.2. A degree formula in the complex case. Let $f : (\mathbb{C}^{n+1}, 0) \rightarrow (\mathbb{C}, 0)$ be a germ of holomorphic function. In the case that $0 \in \mathbb{C}^{n+1}$ is an isolated critical point of f , Milnor considered the topological degree, denote by $\deg_0 \nabla f$, of the normalized gradient vector field

$$(5) \quad \epsilon \frac{\nabla f}{\|\nabla f\|} : S_\epsilon^{2n+1} \rightarrow S_\epsilon^{2n+1},$$

where $\nabla f = (\frac{\partial f}{\partial z_0}, \dots, \frac{\partial f}{\partial z_n})$. Let us denote by $\mu_f := \deg_0 \nabla f$.

This number was named later as “Milnor number” and it has several important meanings. For instance, it is known that the regular fiber $F_\theta = (\frac{f}{\|\nabla f\|})^{-1}(\theta)$ has the homotopy type of a bouquet of n -dimensional spheres and the number of spheres in the bouquet is μ_f . Therefore, the Euler-Poincaré characteristic of the (regular) fiber satisfies the following *Poincaré-Hopf formula*

$$(6) \quad \chi(F_\theta) = 1 + (-1)^n \mu_f.$$

In the search of topological and analytical invariants of complex and real singularities, this type of Poincaré-Hopf formula became a starting point of several others formulae, for isolated and non-isolated singularities, in the local and global settings. Below we will discuss briefly some of them in the local real setting.

2.3. Degree formulae in the real case. In [Kh] Khimshiashvili considered a germ of real analytic function $f : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}, 0)$ with isolated critical point at the origin, and proved that

$$(7) \quad \chi(f^{-1}(\delta) \cap B_\epsilon^n) = 1 - \text{sign}(-\delta)^n \deg_0 \nabla f,$$

where $0 < |\delta| \ll \epsilon \ll 1$ is a regular value, B_ϵ^n stands for the closed ball centered at the origin, ∇f is the gradient vector field of f and $\deg_0 \nabla f$ is the topological degree of the mapping

$$\epsilon \frac{\nabla f}{\|\nabla f\|} : S_\epsilon^{n-1} \rightarrow S_\epsilon^{n-1}.$$

The formula above was extended for mappings with isolated singularity as follows.

Let $F = (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$ be an analytic mapping with isolated critical point at the origin. Then, each coordinate function f_i , for $i = 1, \dots, p$, also has isolated critical point at the origin. Using these notations, formulae (6) and (7) above were extended in the following way:

Theorem 2.11. [ADD, Theorem 1.3, page. 210] *Given $F : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$, $n > p \geq 1$, as above, the following holds true:*

(i) *If n is even, then $\chi(\mathcal{M}_F^T) = 1 - \deg_0 \nabla f_1$. Moreover, we have*

$$\deg_0 \nabla f_1 = \deg_0 \nabla f_2 = \cdots = \deg_0 \nabla f_p.$$

(ii) *If n is odd, then $\chi(\mathcal{M}_F^T) = 1$. Moreover, we have $\deg_0 \nabla f_i = 0$ for $i = 1, 2, \dots, p$.*

Example 2.12 (Case of isolated singularity of holomorphic functions). *Given a germ of holomorphic function $f : (\mathbb{C}^{n+1}, 0) \rightarrow (\mathbb{C}, 0)$ with isolated critical point at origin, we consider the complex variable $z_j = x_j + iy_j$, for $1 \leq j \leq n+1$ and $f = (P, Q) : (\mathbb{R}^{2n+2}, 0) \rightarrow (\mathbb{R}^2, 0)$ where $P = \Re(f)$ and $Q = \Im(f)$ is the real and imaginary part of f , respectively. By Cauchy-Riemann equations, we have that*

$$\nabla P(x, y) = \left(\frac{\partial P(x, y)}{\partial x_1} - i \frac{\partial P(x, y)}{\partial y_1}, \dots, \frac{\partial P(x, y)}{\partial x_{n+1}} - i \frac{\partial P(x, y)}{\partial y_{n+1}} \right),$$

which we can be identified with

$$\nabla P(x, y) = \left(\frac{\partial P(x, y)}{\partial x_1}, -\frac{\partial P(x, y)}{\partial y_1}, \dots, \frac{\partial P(x, y)}{\partial x_{n+1}}, -\frac{\partial P(x, y)}{\partial y_{n+1}} \right).$$

Denote by $H(x, y) := \left(\frac{\partial P(x, y)}{\partial x_1}, \frac{\partial P(x, y)}{\partial y_1}, \dots, \frac{\partial P(x, y)}{\partial x_{n+1}}, \frac{\partial P(x, y)}{\partial y_{n+1}} \right)$ and by $\deg_0 \nabla H$ the topological degree of the map $\epsilon_{\frac{\nabla H}{\|\nabla H\|}} : S_\epsilon^{2n+1} \rightarrow S_\epsilon^{2n+1}$, for all $\epsilon > 0$ small enough. Now, it is easy to see that

$$\deg_0 \nabla P = (-1)^{n+1} \cdot \deg_0 \nabla H$$

and so Milnor's formula (6) follows from Theorem 2.11, item i).

It seems natural to search for similar result for non-isolated singularities. This was done in [DA] and we will explain below the main strategy used to get an analogous formula.

Let us consider $F = (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$, $1 \leq p \leq n-1$, an analytic mapping. Consider $l \in \{1, \dots, p\}$ and $I = \{i_1, \dots, i_l\}$ an l -tuple of pairwise distinct elements of $\{1, \dots, p\}$ and let us denote by f_I the mapping $(f_{i_1}, \dots, f_{i_l}) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^l, 0)$. Suppose that F satisfies Milnor's condition (a) at the origin. Then, we have

$$\Sigma_{f_I} \subset \Sigma_F \subset F^{-1}(0) \subset f_I^{-1}(0),$$

and so by definition the map f_I also satisfies Milnor's condition (a) at the origin.

It is clear that $\Sigma_{f_I, \rho} \subset \Sigma_{F, \rho}$. In [DA] it was proved the following key result:

Lemma 2.13. [DA] *Assume that F satisfies Milnor's conditions (a) and (b) at the origin. Then, for all $l \in \{1, \dots, p\}$ and $I = \{i_1, \dots, i_l\} \subset \{1, \dots, p\}$, the maps $f_I : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^l, 0)$ satisfies Milnor's conditions (a) and (b).*

Proof. See [DA, Lemma 4.1, page 7]. \square

Corollary 2.14. *There exists $\epsilon_0 > 0$ such that, for all $l \in \{1, \dots, p\}$ and $I = \{i_1, \dots, i_l\} \subset \{1, \dots, p\}$, the maps $f_I : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^l, 0)$ have ϵ_0 as a Milnor's radius. Therefore, for all $2 \leq l \leq p$ there exist the Milnor fibrations (see Theorem 2.4 and Corollary 2.5) for the maps $f_I : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^l, 0)$.*

In [DA] several formulae were proved connecting the Euler-Poincaré characteristics of the links of the sets $f_I^{-1}(0)$ and of the Milnor fiber \mathcal{M}_F^T for an analytic map germ F under Milnor's conditions (a) and (b). We remind below some of them.

As above, let us choose $l \in \{1, \dots, p\}$ and an l -tuple $I = \{i_1, \dots, i_l\}$ of pairwise distinct elements of $\{1, \dots, p\}$. We write $J = \{i_1, \dots, i_{l-1}\}$. We also denote by $\text{Lk}^0(V_I)$ (resp. $\text{Lk}^0(V_J)$) the local link of the zero-set of f_I (resp. f_J). If $l = 1$ then $J = \emptyset$ and we put $f_J = 0$.

Proposition 2.15. *We have:*

$$\chi(\text{Lk}^0(V_J)) - \chi(\text{Lk}^0(V_I)) = (-1)^{n-l} 2\chi(\mathcal{M}_F^T).$$

Proof. See [DA, Proposition 7.1, page 10]. \square

Corollary 2.16. *Let $j \in \{1, \dots, p\}$. If n is even, then we have $\chi(\text{Lk}^0(V_{\{j\}})) = 2\chi(\mathcal{M}_F^T)$ and if n is odd, then we have $\chi(\text{Lk}^0(V_{\{j\}})) = 2 - 2\chi(\mathcal{M}_F^T)$.*

Proof. We apply the previous proposition to the case $l = 1$. In this case, if n is even then $\chi(\text{Lk}^0(V_J)) = 0$ and if n is odd then $\chi(\text{Lk}^0(V_J)) = 2$. \square

Let us explain how to apply this result in order to get a degree formula for $\chi(\mathcal{M}_F^T)$.

Given $h_1, \dots, h_s : U \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$ analytic functions, defined in an open neighborhood of the origin U , with $h_1(0) = \dots = h_s(0) = 0$, let $h(x) = h_1(x)^2 + \dots + h_s(x)^2$. Of course, the following equality of analytic sets holds

$$\{x \in U : h_1(x) = \dots = h_s(x) = 0\} = \{x \in U : h(x) = 0\}.$$

Szafraniec in [Sz] considered the function $g(x) = h(x) - c\rho(x)^k$, where $c > 0$ and k an integer, and showed that for k large enough the function g has an isolated singular point at the origin. Moreover, he proved that for all small radius ϵ , the following Poincaré-Hopf type formula holds true:

$$(8) \quad \chi(\{x \in S_\epsilon^{n-1} : h(x) = 0\}) = 1 - \deg_0 \nabla g.$$

From Szafraniec's equation above and Corollary 2.16, we can state a Poincaré-Hopf type formula for local non-isolated singularities as follows:

Proposition 2.17. *Given $F = (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$, $1 \leq p \leq n - 1$, an analytic map germ satisfying Milnor's conditions (a) and (b). There exist $c > 0$ and an integer k such that if $g(x) = f_1^2(x) - c \cdot \rho(x)^k$ then we have,*

- (i) *if n is even, then $\chi(\mathcal{M}_F^T) = \frac{1}{2}(1 - \deg_0 \nabla g)$;*
- (ii) *if n is odd, then $\chi(\mathcal{M}_F^T) = \frac{1}{2}(1 + \deg_0 \nabla g)$.*

Proof. It follows from Corollary 2.16 and Szafraniec's results. \square

3. FIBRATION STRUCTURE AND DEGREE FORMULAE - GLOBAL SETTING

3.1. (Global Milnor) Fibration's structure. It is well known that, for a polynomial holomorphic function $f : \mathbb{C}^{n+1} \rightarrow \mathbb{C}$, there exists a finite set of complex values called the bifurcation set, denoted by $B_f \subset \mathbb{C}$, such that the restriction map $f| : \mathbb{C}^{n+1} \setminus f^{-1}(B_f) \rightarrow \mathbb{C} \setminus B_f$ is a smooth locally trivial fibration. If one takes a closed disc in the target space, $D_R \subset \mathbb{C}$ with $R > 0$ big enough in such a way that B_f is included inside its interior, this fibration induces the so-called *global monodromy fibration of f* ,

$$(9) \quad f| : \mathbb{C}^{n+1} \cap f^{-1}(S_R^1) \rightarrow S_R^1$$

which is also a smooth locally trivial fibration.

In [NZ1] Nemethi and Zaharia considered a kind of regularity condition called *semitame condition* which control the asymptotic behavior of the fibers at infinity. Following Milnor's method for the local case, they proved that for all radii R big enough, denote by $R \gg 1$, the canonical (Milnor) projection

$$(10) \quad \frac{f}{\|f\|} : S_R^{2n+1} \setminus \{f = 0\} \rightarrow S^1$$

is a smooth locally trivial fibration. But, as the authors explained in the introduction in [NZ1] (see Section 4 in [NZ1], for further results), one can check in Broughton's example $f(x, y) = x + x^2y$ that the fiber of the Milnor projection (10) is the thrice punctured 2-sphere and the generic fiber (9) is the twice punctured 2-sphere. So, these two fibrations can not be fiber-equivalent.

In the real case, this fibration structure has been also approached in [ACT2] and more recently in a more general way by the present authors in [DACA]. Below we give the main ideas and results of [ACT2].

Let $F = (f_1, \dots, f_p) : \mathbb{R}^n \rightarrow \mathbb{R}^p$, $2 \leq p \leq m-1$, be a polynomial mapping, $V = F^{-1}(0)$ and for $R \gg 1$, denote by $\text{Lk}^\infty(V) := V \cap S_R^{n-1}$ the link of V at infinity. Let us denote by $\rho : \mathbb{R}^n \rightarrow \mathbb{R}$, $\rho(x) = x_1^2 + \dots + x_n^2$, and so $S_R^{n-1} = \rho^{-1}(R)$.

Consider the (global Milnor's) projection $\frac{F}{\|F\|} : S_R^{n-1} \setminus \text{Lk}^\infty(V) \rightarrow S^{p-1}$ and, as in the local case, also denote by:

- (a) Σ_F the set of critical points of F .
- (b) $M(\frac{F}{\|F\|})$ the set of critical points of the pair $(\frac{F}{\|F\|}, \rho)$ inside $\mathbb{R}^n \setminus V$.
- (c) $M(F)$ the critical locus of the pair (F, ρ) .

With such a definition, the authors in [ACT2] proved a fibration structure on spheres of radii big enough, as follows.

Following the definition stated in [ACT2], we will consider the following conditions:

Condition (A): $\overline{M(F) \setminus V} \cap V$ is bounded in \mathbb{R}^n .

Condition (B): $M(\frac{F}{\|F\|})$ is bounded in \mathbb{R}^n .

Theorem 3.1. *Let $F : \mathbb{R}^n \rightarrow \mathbb{R}^p$ be a real polynomial map such that $\text{codim}_{\mathbb{R}} V = p$ at infinity¹ and assume that Condition (A) holds. Then we have the equivalence:*

- (i) $(\text{Lk}^\infty(V), \frac{F}{\|F\|})$ is an open book decomposition of S_R^{n-1} with singular binding, independent of the high enough radius $R \gg 1$ up to C^∞ isotopy.
- (ii) Condition (B) holds.

Proof. We follow closely the proof given in [ACT2]. We should say that the same idea of this proof was used in [DACA], but to prove a fibration theorem in a more general setting.

Firstly, see that Condition (B) holds if and only if for all $R \gg 1$ the projection mapping

$$\frac{F}{\|F\|} : S_R^{n-1} \setminus \text{Lk}^\infty(V) \rightarrow S^{p-1}$$

is a submersion.

¹For the zero locus $V = F^{-1}(0) \subset \mathbb{R}^n$, we say that “ V has codimension p at infinity” if for any radius $R \gg 1$, $\text{codim}_{\mathbb{R}} V \setminus B_R = p$, in the sense that every irreducible component of V has this property.

By the Curve Selection Lemma, Condition (A) means that: there exists $\delta > 0$ small enough and a closed disc B_δ^p centered at origin such that

$$F| : F^{-1}(B_\delta^p - \{0\}) \cap S_R^{n-1} \rightarrow B_\delta^p - \{0\}$$

is a surjective proper and smooth submersion.

The implication (i) \Rightarrow (ii) is trivial, because if we suppose that $\frac{F}{\|F\|} : S_R^{n-1} \setminus \text{Lk}^\infty(V) \rightarrow S^{p-1}$ is a locally trivial fibration, then it is a submersion and so Condition (B) follows.

Let us prove the converse. We can assume that $\text{Lk}^\infty(V)$ is not empty: in fact, in the case it is empty, Condition (A) is always satisfied and by Condition (B), we have that $\frac{F}{\|F\|} : S_R^{n-1} \rightarrow S^{p-1}$ is a proper submersion and so onto, since S^{p-1} is connected. Hence (i) follows by Ehresmann's theorem.

In the case $\text{Lk}^\infty(V)$ is not empty, the projection $\frac{F}{\|F\|} : S_R^{n-1} \setminus \text{Lk}^\infty(V) \rightarrow S^{p-1}$ is not proper and we can not use Ehresmann's theorem. Nevertheless, the mapping $F| : F^{-1}(B_\delta^p - \{0\}) \cap S_R^{n-1} \rightarrow B_\delta^p - \{0\}$ is a surjective proper submersion. So, by Ehresmann's theorem, the mapping

$$(11) \quad F| : F^{-1}(B_\delta^p - \{0\}) \cap S_R^{n-1} \rightarrow B_\delta^p - \{0\}$$

is a locally trivial fibration. Now, we can compose it with the radial projection $\pi_1 : B_\delta^p - \{0\} \rightarrow S^{p-1}$, $\pi_1(y) = \frac{y}{\|y\|}$, to get that

$$(12) \quad \frac{F}{\|F\|} : F^{-1}(B_\delta^p - \{0\}) \cap S_R^{n-1} \rightarrow S^{p-1}$$

is a locally trivial fibration, as well.

Fibration (11) yields that the map

$$(13) \quad \frac{F}{\|F\|} : F^{-1}(S_\delta^{p-1}) \cap S_R^{n-1} \rightarrow S^{p-1}$$

is also a locally trivial fibration and therefore surjective.

This implies that

$$(14) \quad \frac{F}{\|F\|} : S_R^{n-1} \setminus F^{-1}(\mathring{B}_\delta^p) \rightarrow S^{p-1}$$

is surjective and proper, where \mathring{B}_δ^p denotes the open disk for some $0 < \delta \ll \frac{1}{R}$. So, by using Condition (B), the mapping $\frac{F}{\|F\|}$ is a smooth submersion. Therefore, we have a locally trivial fibration by Ehresmann's theorem.

Now we can glue fibrations (12) and (14) along the common boundary $F^{-1}(S_\delta^{p-1}) \cap S_R^{n-1}$, using fibration (13), to get the item (i). \square

Remark 3.2. *As mentioned above, inspired by (the local) Milnor's conditions and the global conditions introduced in [ACT2], the present authors in [DACA] introduced two conditions that produce open book structures on C^2 semi-algebraic manifolds, generalizing and unifying this way open book structures on spheres of big or small radii.*

3.2. A degree formula in the complex case. In [Br, HZ, NZ1, NZ2] the authors considered a polynomial holomorphic function $f : \mathbb{C}^{n+1} \rightarrow \mathbb{C}$ under the so-called tame, M -tame and semitame conditions. We do not intend to give more details in this direction, but we remind briefly the definitions of these conditions and give some topological results concerning the (global) Milnor fibers.

If one fixes coordinates $z = (z_0, \dots, z_n)$, then one can consider the following quotient algebra

$$\mathcal{Q}_f = \frac{\mathbb{C}[z_0, \dots, z_n]}{(\frac{\partial f}{\partial z_0}, \dots, \frac{\partial f}{\partial z_n})},$$

where $\mathbb{C}[z_0, \dots, z_n]$ denotes the ring of polynomial holomorphic functions and $(\frac{\partial f}{\partial z_0}, \dots, \frac{\partial f}{\partial z_n})$ denotes the ideal spanned by the partial derivatives of f .

It is well known that f has only finitely many isolated singular points if and only if the complex dimension of the quotient algebra $\dim_{\mathbb{C}} \mathcal{Q}_f$ is finite. This dimension is called the total Milnor number and it is denoted as in the local case by μ_f . As in the local case, the number μ_f is equal to the topological degree, denote by $\deg_{\infty} \nabla f$, of the normalized gradient vector field

$$(15) \quad R \frac{\nabla f}{\|\nabla f\|} : S_R^{2n+1} \rightarrow S_R^{2n+1}.$$

Denote by $\overline{\nabla}(f) = (\overline{\frac{\partial f}{\partial z_0}}, \dots, \overline{\frac{\partial f}{\partial z_n}})$ and the so-called (complex) Milnor set by $M(f) = \{z \in \mathbb{C}^{n+1}; \overline{\nabla}(f) = \lambda z\}$ for some $\lambda \in \mathbb{C}$.

Under the notations above, consider the following condition $(*)$: for every sequence $\{z_k\} \subset M(f)$ such that $\|z_k\| \rightarrow +\infty$, $\overline{\nabla}(f)(z_k) \rightarrow 0$.

Definition 3.3. *We say that a polynomial function f under condition $(*)$ is:*

- (i) *M -tame if $|f(z_k)| \rightarrow +\infty$.*
- (ii) *semitame if $|f(z_k)| \rightarrow c$, for some $c \in \mathbb{C}$, then $c = 0$.*

Of course, if f is M -tame, then it is semitame. But, the converse is not true, see for instance [NZ1].

Theorem 3.4 ([NZ1, NZ2] see also [HZ]). *Let $f : \mathbb{C}^{n+1} \rightarrow \mathbb{C}$ be a M -tame holomorphic polynomial function. Then, the following holds true:*

- (i) *the bifurcation B_f is equal to the singular locus Σ_f .*
- (ii) *for each value $w \in \mathbb{C} \setminus B_f$, the (typical) fiber $f^{-1}(w)$ has the homotopy type of a bouquet of μ_f n -dimensional spheres.*
- (iii) *the fibration (10) is fiber-equivalent to the global monodromy fibration of f .*

So, it follows from item [(ii)] above that for such M -tame class of polynomial we still have the following Poincaré-Hopf type formula

$$\chi(F_\theta) = 1 + (-1)^n \mu_f,$$

where F_θ is the fiber of fibration (10).

3.3. Degree formulae in the real case. Inspired by the formulae proved in local case and in the global complex case, we present below a degree formula for the Euler characteristic of the real Milnor fiber in a big sphere. The strategy is the same as in the local case. First we need to establish global versions of Szafraniec's theorem [Sz]. Note that the results below are new.

3.3.1. On the link at infinity of a closed semi-algebraic set. We establish several degree formulae for the Euler characteristic of the link at infinity of a closed semi-algebraic set. If $X \subset \mathbb{R}^n$ is a semi-algebraic set, then we denote by $\text{Lk}^\infty(X)$ its link at infinity.

Let $f : \mathbb{R}^n \rightarrow \mathbb{R}$ be a C^2 -semi-algebraic function. We assume that 0 is a critical value of f . We denote by $\Sigma_f = (\nabla f)^{-1}(0)$ the set of critical points of f . We remark that $\Sigma_f \cap f^{-1}(0)$ may not be compact.

Let $\omega(x) = 1 + \frac{1}{2}(x_1^2 + \cdots + x_n^2)$. Note that $\nabla \omega(x) = x$ and $\omega(x) \geq 1$. Let

$$\Gamma_{f,\omega} = \{x \in \mathbb{R}^n \mid \text{rank}[\nabla f(x), \nabla \omega(x)] < 2\}.$$

We have $\Sigma_f \subset \Gamma_{f,\omega}$.

Lemma 3.5. *There is $k \in \mathbb{N}$ such that for all $x \in \Gamma_{f,\omega} \setminus f^{-1}(0)$,*

$$|f(x)| > \frac{1}{\omega(x)^k},$$

for $|x| \gg 1$.

Proof. Let r_0 be the greatest critical value of ω . We set $\tilde{S}_r = \omega^{-1}(r)$. Let $\beta :]r_0, +\infty[\rightarrow \mathbb{R}$ be defined by

$$\beta(r) = \inf \left\{ |f(x)| \mid x \in \tilde{S}_r \cap (\Gamma_{f,\omega} \setminus f^{-1}(0)) \right\}.$$

The function β is semi-algebraic. Furthermore $\beta > 0$ because for $r > r_0$, $f|_{\tilde{S}_r}$ has a finite number of critical values. Thus the function $\frac{1}{\beta}$ is also semi-algebraic. Hence there exist $r_1 \geq r_0$ and $k_0 \in \mathbb{N}$ such that $\frac{1}{\beta} < r^k$, for $r \geq r_1$ and $k \geq k_0$. This implies that $\beta(r) > \frac{1}{r^k}$ for $r \geq r_1$ and $k \geq k_0$. We can conclude that for $r \geq r_1$ and $k \geq k_0$,

$$|f(x)| > \frac{1}{\omega(x)^k},$$

for $x \in \tilde{S}_r \cap (\Gamma_{f,\omega} \setminus f^{-1}(0))$. \square

Let $g_-(x) = f(x) - \frac{1}{\omega(x)^k}$. Note that $\Gamma_{f,\omega} = \Gamma_{g_-,\omega}$.

Lemma 3.6. *For $R \gg 1$, $\chi(\{g_- \leq 0\} \cap \tilde{S}_R) = \chi(\{f \leq 0\} \cap \tilde{S}_R)$.*

Proof. Let $R \gg 1$ be such that for all $x \in \Gamma_{f,\omega} \setminus f^{-1}(0) \cap \{\omega(x) \geq R\}$, $|f(x)| > \frac{1}{\omega(x)^k}$. Let $N_f^{\leq} = \{x \in \tilde{S}_R \mid f(x) \leq 0\}$ and $N_{g_-}^{\leq} = \{x \in \tilde{S}_R \mid g_-(x) \leq 0\}$. For $x \in \tilde{S}_R$, we have

$$g_-(x) \leq 0 \Leftrightarrow f(x) - \frac{1}{R^k} \leq 0 \Leftrightarrow f(x) \leq \frac{1}{R^k},$$

and so $N_f^{\leq} \subset N_{g_-}^{\leq}$. Furthermore if $0 < f(x) \leq \frac{1}{R^k}$ then $x \notin \Gamma_{f,\omega} \setminus f^{-1}(0)$ and therefore $\{f(x) \leq \frac{1}{R^k}\} \cap \tilde{S}_R$ retracts by deformation to $\{f(x) \leq 0\} \cap \tilde{S}_R$. We get the result. \square

Corollary 3.7. *We have $\chi(\text{Lk}^\infty(\{g_- \leq 0\})) = \chi(\text{Lk}^\infty(\{f \leq 0\}))$.*

\square

Let $g_+(x) = f(x) + \frac{1}{\omega(x)^k}$. Note that $\Gamma_{f,\omega} = \Gamma_{g_+,\omega}$.

Lemma 3.8. *For $R \gg 1$, $\chi(\{g_+ \geq 0\} \cap \tilde{S}_R) = \chi(\{f \geq 0\} \cap \tilde{S}_R)$.*

Proof. Let $R \gg 1$ be such that for all $x \in \Gamma_{f,\omega} \setminus f^{-1}(0) \cap \{\omega(x) \geq R\}$, $|f(x)| > \frac{1}{\omega(x)^k}$. Let $N_f^{\geq} = \{x \in \tilde{S}_R \mid f(x) \geq 0\}$ and $N_{g_+}^{\geq} = \{x \in \tilde{S}_R \mid g_+(x) \geq 0\}$. For $x \in \tilde{S}_R$, we have

$$g_+(x) \geq 0 \Leftrightarrow f(x) + \frac{1}{R^k} \geq 0 \Leftrightarrow f(x) \geq -\frac{1}{R^k},$$

and so $N_f^{\geq} \subset N_{g_+}^{\geq}$. Furthermore if $0 > f(x) \geq -\frac{1}{R^k}$ then $x \notin \Gamma_{f,\omega} \setminus f^{-1}(0)$ and therefore $\{f(x) \geq -\frac{1}{R^k}\} \cap \tilde{S}_R$ retracts by deformation to $\{f(x) \geq 0\} \cap \tilde{S}_R$. We get the result. \square

Corollary 3.9. *We have $\chi(\text{Lk}^\infty(\{g_+ \geq 0\})) = \chi(\text{Lk}^\infty(\{f \geq 0\}))$.*

\square

Lemma 3.10. *The sets $(\nabla g_-)^{-1}(0) \cap \{g_- = 0\}$ and $(\nabla g_+)^{-1}(0) \cap \{g_+ = 0\}$ are compact.*

Proof. If $x \in (\nabla g_-)^{-1}(0) \cap \{g_- = 0\}$ then $x \in \Gamma_{g_-, \omega} = \Gamma_{f, \omega}$ and $f(x) = \frac{1}{\omega(x)^k} \neq 0$. So $x \in \Gamma_{f, \omega} \setminus f^{-1}(0)$. But there exists $R \geq r_1$ such that $|f(x)| > \frac{1}{\omega(x)^k}$ if $\rho(x) \geq R$ and $x \in \Gamma_{f, \omega} \setminus f^{-1}(0)$. We conclude that

$$\nabla(g_-)^{-1}(0) \cap \{g_- = 0\} \subset \tilde{B}_R,$$

where $\tilde{B}_R = \{\omega \leq R\}$. \square

We make the assumption that $f(0) > 1$.

Lemma 3.11. *We have $g_-(0) > 0$ and $g_+(0) > 0$.*

Proof. We have $g_-(0) = f(0) - 1$ and $g_+(0) = f(0) + 1$. \square

Let H_- and $H_+ : \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1}$ be defined by

$$H_-(\lambda, x) = (\lambda x + \nabla g_-, g_-) \text{ and } H_+(\lambda, x) = (\lambda x + \nabla g_+, g_+).$$

Lemma 3.12. *The sets $H_-^{-1}(0)$ and $H_+^{-1}(0)$ are compact.*

Proof. See [Du1], Lemma 5.4 and Remark 5.11. \square

Let δ_- be a small regular value of g_- . Let $R_- \gg 1$ be such that $\{g_- = 0\} \cap \tilde{B}_{R_-}$ is a retract by deformation of $\{g_- = 0\}$, $\{g_- \leq 0\} \cap \tilde{B}_{R_-}$ is a retract by deformation of $\{g_- \leq 0\}$ and $\{g_- \geq 0\} \cap \tilde{B}_{R_-}$ is a retract by deformation of $\{g_- \geq 0\}$.

Proposition 3.13. *If n is even, we have*

$$\chi(\{g_- = \delta_-\} \cap \tilde{B}_{R_-}) = \deg_\infty H_-.$$

If n is odd, we have

$$\chi(\{g_- \geq \delta_-\} \cap \tilde{B}_{R_-}) - \chi(\{g_- \leq \delta_-\} \cap \tilde{B}_{R_-}) = 1 - \deg_\infty H_-.$$

Proof. Apply equalities **(A)** and **(D)** in [Du1], page 332, and use the fact that $g_-(0) > 0$. \square

If n is even, we have

$$\begin{aligned} \chi(\{g_- = \delta_-\} \cap \tilde{B}_{R_-}) &= \frac{1}{2} \chi(\{g_- = \delta_-\} \cap \tilde{S}_{R_-}) = \chi(\{g_- \leq \delta_-\} \cap \tilde{S}_{R_-}) = \\ &= \chi(\{g_- \leq 0\} \cap \tilde{S}_{R_-}) = \chi(\text{Lk}^\infty(\{g_- \leq 0\})). \end{aligned}$$

If n is odd, we have

$$\chi(\{g_- \geq \delta_-\} \cap \tilde{B}_{R_-}) - \chi(\{g_- \leq \delta_-\} \cap \tilde{B}_{R_-}) =$$

$$\frac{1}{2} \left[\chi(\{g_- \geq \delta_-\} \cap \tilde{S}_{R_-}) - \chi(\{g_- \leq \delta_-\} \cap \tilde{S}_{R_-}) \right].$$

Since,

$$\chi(\tilde{S}_{R_-}) = 2 = \chi(\{g_- \geq \delta_-\} \cap \tilde{S}_{R_-}) + \chi(\{g_- \leq \delta_-\} \cap \tilde{S}_{R_-}),$$

we find that $\chi(\{g_- \geq \delta_-\} \cap \tilde{S}_{R_-}) = 2 - \chi(\{g_- \leq \delta_-\} \cap \tilde{S}_{R_-})$ and that

$$\begin{aligned} \chi(\{g_- \geq \delta_-\} \cap \tilde{B}_{R_-}) - \chi(\{g_- \leq \delta_-\} \cap \tilde{B}_{R_-}) &= 1 - \chi(\{g_- \leq \delta_-\} \cap \tilde{S}_{R_-}) = \\ &= 1 - \chi(\{g_- \leq 0\} \cap \tilde{S}_{R_-}) = 1 - \chi(\text{Lk}^\infty(\{g_- \leq 0\})). \end{aligned}$$

Corollary 3.14. *We have*

$$\chi(\text{Lk}^\infty(\{g_- \leq 0\})) = \chi(\text{Lk}^\infty(\{f \leq 0\})) = \deg_\infty H_-.$$

□

Let δ_+ be a small regular value of g_+ . Let $R_+ \gg 1$ be such that $\{g_+ = 0\} \cap \tilde{B}_{R_+}$ is a retract by deformation of $\{g_+ = 0\}$, $\{g_+ \leq 0\} \cap \tilde{B}_{R_+}$ is a retract by deformation of $\{g_+ \leq 0\}$ and $\{g_+ \geq 0\} \cap \tilde{B}_{R_+}$ is a retract by deformation of $\{g_+ \geq 0\}$.

Proposition 3.15. *If n is even, we have*

$$\chi(\{g_+ = \delta_+\} \cap \tilde{B}_{R_+}) = \deg_\infty H_+.$$

If n is odd, we have

$$\chi(\{g_+ \geq \delta_+\} \cap \tilde{B}_{R_+}) - \chi(\{g_+ \leq \delta_+\} \cap \tilde{B}_{R_+}) = 1 - \deg_\infty H_+.$$

Proof. Apply equalities **(A)** and **(D)** in [Du1], page 332, and use the fact that $g_+(0) > 0$. □

Corollary 3.16. *If n is even, we have*

$$\chi(\text{Lk}^\infty(\{f \geq 0\})) = \deg_\infty H_+.$$

If n is odd, we have

$$\chi(\text{Lk}^\infty(\{f \geq 0\})) = 2 - \deg_\infty H_+.$$

Proof. If n is even, we apply the same proof as for $\text{Lk}^\infty(\{f \leq 0\})$.

If n is odd, we remark that

$$\begin{aligned} \chi(\{g_+ \geq \delta_+\} \cap \tilde{B}_{R_+}) - \chi(\{g_+ \leq \delta_+\} \cap \tilde{B}_{R_+}) &= \\ \chi(\{g_+ \geq \delta_+\} \cap \tilde{S}_{R_+}) - 1 &= \chi(\text{Lk}^\infty(\{f \geq 0\})) - 1 = 1 - \deg_\infty H_+. \end{aligned}$$

□

Corollary 3.17. *If n is even, we have*

$$\chi(\text{Lk}^\infty(\{f = 0\})) = \deg_\infty H_- + \deg_\infty H_+.$$

If n is odd, we have

$$\chi(\text{Lk}^\infty(\{f = 0\})) = \deg_\infty H_- - \deg_\infty H_+.$$

Proof. Use the equality

$$\chi(S^{n-1}) = \chi(\text{Lk}^\infty(\{f \geq 0\})) + \chi(\text{Lk}^\infty(\{f \leq 0\})) - \chi(\text{Lk}^\infty(\{f = 0\})),$$

and the previous corollaries. \square

Application: Let $X \subset \mathbb{R}^n$ be a closed semi-algebraic set. There exists a C^2 -semi-algebraic function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ such that $X = f^{-1}(0)$ and $f \geq 0$. By a change of origin if necessary, we can assume that $f(0) > 1$. In this case, $g_+ > 0$ and so $\deg_\infty H_+ = 0$.

Corollary 3.18. *We have $\chi(\text{Lk}^\infty(X)) = \deg_\infty H_-$.*

\square

Now we return to the general case. The functions g_- and g_+ are semi-algebraic but not polynomial even if f is a polynomial. Let G_- and G_+ be defined by

$$G_-(x) = \omega(x)^k g_-(x) = \omega(x)^k f(x) - 1,$$

and

$$G_+(x) = \omega(x)^k g_+(x) = \omega(x)^k f(x) + 1.$$

If f is a polynomial then so are G_- and G_+ . Furthermore, $\{G_- = 0\} = \{g_- = 0\}$, $\{G_- \leq 0\} = \{g_- \leq 0\}$, $\{G_- \geq 0\} = \{g_- \geq 0\}$ and $\{G_+ = 0\} = \{g_+ = 0\}$, $\{G_+ \leq 0\} = \{g_+ \leq 0\}$, $\{G_+ \geq 0\} = \{g_+ \geq 0\}$.

Lemma 3.19. *The sets $(\nabla G_-)^{-1}(0) \cap \{G_- = 0\}$ and $(\nabla G_+)^{-1}(0) \cap \{G_+ = 0\}$ are compact.*

Proof. We have

$$\nabla G_-(x) = k\omega(x)^{k-1}g_-(x)\nabla\omega(x) + \omega(x)^k\nabla g_-(x).$$

If $G_-(x) = 0$ then $g_-(x) = 0$ and so $\nabla G_-(x) = \omega(x)^k\nabla g_-(x)$. We see that $(\nabla G_-)^{-1}(0) \cap \{G_- = 0\} = (\nabla g_-)^{-1}(0) \cap \{g_- = 0\}$, which is compact. \square

Let L_- and $L_+ : \mathbb{R}^{n+1} \rightarrow \mathbb{R}^{n+1}$ be defined by

$$L_-(\lambda, x) = (\lambda x + \nabla G_-, G_-) \text{ and } L_+(\lambda, x) = (\lambda x + \nabla G_+, G_+).$$

Lemma 3.20. *The sets $L_-^{-1}(0)$ and $L_+^{-1}(0)$ are compact.*

Proof. See [Du1], Lemma 5.4 and Remark 5.11. \square

Corollary 3.21. *We have*

$$\begin{aligned} \chi(\text{Lk}^\infty(\{f \leq 0\})) &= \deg_\infty L_-, \\ \chi(\text{Lk}^\infty(\{f \geq 0\})) &= \deg_\infty L_+, \text{ if } n \text{ is even,} \\ \chi(\text{Lk}^\infty(\{f \geq 0\})) &= 2 - \deg_\infty L_+, \text{ if } n \text{ is odd,} \\ \chi(\text{Lk}^\infty(\{f = 0\})) &= \deg_\infty L_- + \deg_\infty L_+, \text{ if } n \text{ is even,} \\ \chi(\text{Lk}^\infty(\{f = 0\})) &= \deg_\infty L_- - \deg_\infty L_+, \text{ if } n \text{ is odd.} \end{aligned}$$

□

Application: Let $X \subset \mathbb{R}^n$ be a closed semi-algebraic set. There exists a C^2 -semi-algebraic function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ such that $X = f^{-1}(0)$ and $f \geq 0$. By a change of origin if necessary, we can assume that $f(0) > 1$. In this case, $G_+ > 0$ and so $\deg_\infty L_+ = 0$.

Corollary 3.22. *We have $\chi(\text{Lk}^\infty(X)) = \deg_\infty L_-$.*

Next we focus on the case when the C^2 semi-algebraic function is semi-tame.

Definition 3.23. *Let $f : \mathbb{R}^n \rightarrow \mathbb{R}$ be a C^2 -semi-algebraic function. We say that f is semi-tame if for any sequence of points $(x_n)_{n \in \mathbb{N}}$ in $\Gamma_{f,\omega}$ such that $|x_n| \rightarrow +\infty$, we have $\lim_{n \rightarrow +\infty} |f(x_n)| = 0$ or $+\infty$.*

Lemma 3.24. *If $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is semi-tame then $(\nabla f)^{-1}(0) \setminus \{f = 0\}$ is compact.*

Proof. Let $\alpha \neq 0$ be a critical value of f . Let $x \in f^{-1}(\alpha) \cap (\nabla f)^{-1}(0)$, x belongs to $\Gamma_{f,\omega}$. If $f^{-1}(\alpha) \cap \nabla f^{-1}(0)$ is not compact then there exists a sequence of points $(x_n)_{n \in \mathbb{N}}$ such that $|x_n| \rightarrow +\infty$, $f(x_n) = \alpha$ and $\nabla f(x_n) = 0$. But $x_n \in \Gamma_{f,\omega}$, this contradicts the semi-tameness of f . □

Lemma 3.25. *The functions g_- and g_+ are semi-tame.*

Proof. We know that $\Gamma_{g_-,\omega} = \Gamma_{f,\omega}$. Let $(x_n)_{n \in \mathbb{N}}$ be a sequence of points in $\Gamma_{g_-,\omega}$ such that $|x_n| \rightarrow +\infty$. Then $x_n \in \Gamma_{f,\omega}$ and $|x_n| \rightarrow +\infty$ so $\lim_{n \rightarrow +\infty} |f(x_n)| = 0$ or $+\infty$. But $g_-(x_n) = f(x_n) - \frac{1}{\omega(x_n)^k}$ so

$$\lim_{n \rightarrow +\infty} |g_-(x_n)| = 0 \text{ or } +\infty.$$

□

Corollary 3.26. *The sets $(\nabla g_-)^{-1}(0)$ and $(\nabla g_+)^{-1}(0)$ are compact.*

Proof. The function g_- is semi-tame so $(\nabla g_-)^{-1}(0) \setminus \{g = 0\}$ is compact. We know that $(\nabla g_-)^{-1}(0) \cap \{g = 0\}$ is compact. □

In [Du3], the author introduced three sets $\Lambda_h^<$, $\Lambda_h^=$ and $\Lambda_h^>$ for a C^2 semi-algebraic function h . They are defined as follows: for $* \in \{<, =, >\}$,

$$\Lambda_h^* = \left\{ \alpha \in \mathbb{R} \mid \beta \mapsto \chi(\text{Lk}^\infty(X \cap \{h * \beta\})) \text{ is not constant} \right. \\ \left. \text{in a neighborhood of } \alpha \right\}.$$

By [Du3], Lemma 3.12, we have $\Lambda_{g_-}^< \subset \{0\}$, $\Lambda_{g_-}^> \subset \{0\}$ and $\Lambda_{g_-}^= \subset \{0\}$ since g_- is semi-tame.

Proposition 3.27. *Let $\alpha_- \in]-\infty, 0[$ and $\alpha_+ \in]0, +\infty[$. We have*

$$\chi(\text{Lk}^\infty(\{g_- \leq \alpha_-\})) + \chi(\text{Lk}^\infty(\{g_- \leq \alpha_+\})) - \chi(\text{Lk}^\infty(\{g_- \leq 0\})) = 1 - \deg_\infty \nabla g_-.$$

Proof. See [Du3], Theorem 3.16. □

Lemma 3.28. *Let $\alpha \neq 0$. We have*

$$\chi(\text{Lk}^\infty(\{g_- \leq \alpha\})) = \chi(\text{Lk}^\infty(\{f \leq \alpha\})).$$

Proof. We assume first that $\alpha < 0$. Furthermore, we can suppose that $\frac{1}{2}\alpha + 1 < 0$ because the function $\beta \mapsto \chi(\text{Lk}^\infty(X \cap \{f \leq \beta\}))$ is constant on $] -\infty, 0[$ by the semi-tameness of f . The function g_- is semi-tame so if $(x_n)_{n \in \mathbb{N}}$ is a sequence of points in $\Gamma_{g_-, \omega}$ such that $|x_n| \rightarrow +\infty$ and $g(x_n) \leq \frac{1}{2}\alpha$ then $\lim_{n \rightarrow +\infty} g_-(x_n) = -\infty$. Since $\Gamma_{f, \omega} = \Gamma_{g_-, \omega}$ and f is semi-tame, we also have $\lim_{n \rightarrow +\infty} f(x_n) = -\infty$ because $f(x_n) \leq \frac{1}{2}\alpha + 1 < 0$. So there exists $R_0 \gg 1$ such that for all $R \geq R_0$, $f(x) \leq 2\alpha$ and $g(x) \leq 2\alpha$ for $x \in \tilde{S}_R \cap \Gamma_{g_-, \omega} \cap \{g_- \leq \frac{1}{2}\alpha\}$. So $\text{Lk}^\infty(\{g_- \leq \alpha\})$ is homeomorphic to $\{g_- \leq \alpha\} \cap \tilde{S}_R$ and $\text{Lk}^\infty(\{f \leq \alpha\})$ is homeomorphic to $\{f \leq \alpha\} \cap \tilde{S}_R$ for any $R \geq R_0$. But $\{g_- \leq \alpha\} \cap \tilde{S}_R = \{f \leq \alpha + \frac{1}{R^k}\} \cap \tilde{S}_R$. Since $\tilde{S}_R \cap \Gamma_{f, \omega} \cap \{\alpha \leq f \leq \alpha + \frac{1}{R^k}\}$ is empty, the set $\{f \leq \alpha + \frac{1}{R^k}\} \cap \tilde{S}_R$ is homeomorphic to $\{f \leq \alpha\} \cap \tilde{S}_R$.

If $\alpha > 0$ the proof is the same, replacing $\{g \leq \frac{1}{2}\alpha\}$ with $\{g \geq \frac{1}{2}\alpha\}$ and taking R such that $\alpha + \frac{1}{R^k} < 2\alpha$. □

Corollary 3.29. *Let $\alpha_- \in]-\infty, 0[$ and $\alpha_+ \in]0, +\infty[$. We have*

$$\chi(\text{Lk}^\infty(\{f \leq \alpha_-\})) + \chi(\text{Lk}^\infty(\{f \leq \alpha_+\})) - \chi(\text{Lk}^\infty(\{f \leq 0\})) = 1 - \deg_\infty \nabla g_-.$$

□

Similarly, we can state:

Corollary 3.30. *Let $\alpha_- \in]-\infty, 0[$ and $\alpha_+ \in]0, +\infty[$. We have*

$$\chi(\text{Lk}^\infty(\{f \geq \alpha_-\})) + \chi(\text{Lk}^\infty(\{f \geq \alpha_+\})) - \chi(\text{Lk}^\infty(\{f \geq 0\})) = 1 - (-1)^n \deg_\infty \nabla g_+.$$

□

Corollary 3.31. *Let $\alpha_- \in]-\infty, 0[$ and $\alpha_+ \in]0, +\infty[$. We have*

$$\chi(\text{Lk}^\infty(\{f = \alpha_-\})) + \chi(\text{Lk}^\infty(\{f = \alpha_+\})) - \chi(\text{Lk}^\infty(\{f = 0\})) = 2 - \chi(S^{n-1}) - (\deg_\infty \nabla g_- + (-1)^n \deg_\infty \nabla g_+).$$

Proof. Use the previous two corollaries and the Mayer-Vietoris sequence. □

Application: Let $X \subset \mathbb{R}^n$ be a closed semi-algebraic set. There exists a C^2 -semi-algebraic function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ such that $X = f^{-1}(0)$ and $f \geq 0$. By a change of origin if necessary, we can assume that $f(0) > 1$.

Lemma 3.32. *There exists a C^2 -semi-algebraic function $\Phi : \mathbb{R}^n \rightarrow \mathbb{R}$ such that*

- (a) $X = \Phi^{-1}(0)$ and $\Phi \geq 0$,
- (b) *for any sequence of points $(x_n)_{n \in \mathbb{N}}$ in $\Gamma_{\Phi, \omega} \setminus X$ such that $|x_n| \rightarrow +\infty$, we have $\lim_{n \rightarrow +\infty} |\Phi(x_n)| = +\infty$.*

Moreover one can take $\Phi = \omega^K f$ with $K \gg 1$.

Proof. Same proof as Lemma 3.5 (see also [Du2], Proposition 7.1). \square

Corollary 3.33. *The function Φ is semi-tame.*

\square

Let us remark that

- (a) $\{\Phi \leq \alpha_-\}$ and $\{\Phi = \alpha_-\}$ are empty,
- (b) $\{\Phi \geq \alpha_-\} = \{\Phi \geq 0\}$,
- (c) $\{\Phi \leq 0\} = \{\Phi = 0\}$,
- (d) If $\alpha_+ > 0$ is small enough then $\text{Lk}^\infty(\{\Phi \leq \alpha_+\})$ retracts by deformation to $\text{Lk}^\infty(\{\Phi = 0\})$.

In this situation, the above corollaries applied to Φ become the following corollaries.

Corollary 3.34. *We have $\deg_\infty \nabla g_- = 1$.*

\square

Corollary 3.35. *We have*

$$\chi(\text{Lk}^\infty(\{\Phi \geq \alpha_+\})) = 1 - (-1)^n \deg_\infty \nabla g_+.$$

\square

Corollary 3.36. *We have*

$$\chi(\text{Lk}^\infty(\{\Phi = \alpha_+\})) - \chi(\text{Lk}^\infty(X)) = 1 - \chi(S^{n-1}) - (-1)^n \deg_\infty \nabla g_+.$$

\square

Here we can state the global version of Szafraniec's theorem [Sz].

Corollary 3.37. *We have*

$$\chi(\text{Lk}^\infty(X)) = 1 - \deg_\infty \nabla g_+.$$

Proof. If n is odd, $\text{Lk}^\infty(\{\Phi = \alpha_+\})$ is a compact odd-dimensional manifold and $\chi(S^{n-1}) = 2$.

If n is even, $\chi(S^{n-1}) = 0$. Moreover

$$\chi(\text{Lk}^\infty(\{\Phi = \alpha_+\})) = 2\chi(\text{Lk}^\infty(\{\Phi \geq \alpha_+\})) = 2 - 2\deg_\infty \nabla g_+.$$

□

3.3.2. Applications for the global Milnor fiber on the spheres. Let $F = (f_1, \dots, f_p) : \mathbb{R}^n \rightarrow \mathbb{R}^p$ be a C^2 semi-algebraic mapping such that Conditions (A) and (B) hold. In [DACA] Corollary 4.3, the authors proved a global version of Corollary 2.16.

Proposition 3.38. *Let $j \in \{1, \dots, p\}$. If n is even, then we have $\chi(\text{Lk}^\infty(f_j^{-1}(0))) = 2\chi(\mathcal{M}_{\frac{F}{\|F\|}}^S)$ and if n is odd, then we have $\chi(\text{Lk}^\infty(f_j^{-1}(0))) = 2 - 2\chi(\mathcal{M}_{\frac{F}{\|F\|}}^S)$.*

□

Applying this result and Corollary 3.37, we can state a Poincaré-Hopf formula for $\mathcal{M}_{\frac{F}{\|F\|}}^S$.

Proposition 3.39. *Given $F = (f_1, \dots, f_p) : (\mathbb{R}^n, 0) \rightarrow (\mathbb{R}^p, 0)$, $1 \leq p \leq n-1$, a C^2 semi-algebraic mapping such that Conditions (A) and (B) hold. Assume for instance that $f_1(0) > 1$. There exist two integers $K, k > 0$ such that if $g_+(x) = \omega(x)^K f_1^2(x) + \frac{1}{\omega(x)^k}$ then we have,*

- (i) *if n is even, then $\chi(\mathcal{M}_{\frac{F}{\|F\|}}^S) = \frac{1}{2}(1 - \deg_\infty \nabla g_+)$;*
- (ii) *if n is odd, then $\chi(\mathcal{M}_{\frac{F}{\|F\|}}^S) = \frac{1}{2}(1 + \deg_\infty \nabla g_+)$.*

The authors would like to acknowledge Professor Takashi Nishimura for invite them to submit a paper to RIMS proceedings. Thanks !
